

Improving Background Estimation for Di-Higgs Searches with ATLAS

PHYS 437B Presentations

13 January, 2020

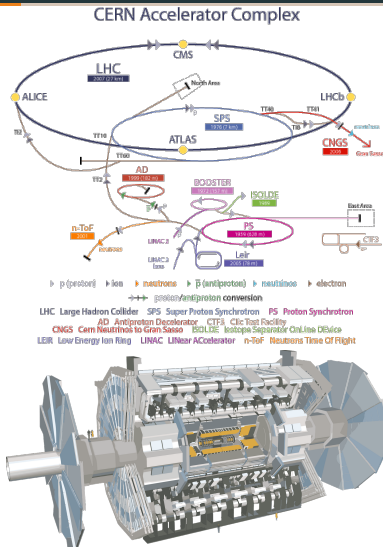

Callum McCracken

Supervisor: Maximilian Swiatlowski

Co-Supervisor: Eduardo Martin-Martinez

Collaborators: Todd Seiss, Mel Shochet

Overview: Higgs Research

Standard Model of Elementary Particles

	three generations of matter (fermions)			interactions / force carriers (bosons)	
	I	II	III		
QUARKS	mass $\approx 2.2 \text{ MeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$ u up	mass $\approx 1.28 \text{ GeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$ c charm	mass $\approx 173.1 \text{ GeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$ t top	mass 0 charge 0 spin 1 g gluon	mass $\approx 124.97 \text{ GeV}/c^2$ charge 0 spin 0 H higgs
	mass $\approx 4.7 \text{ MeV}/c^2$ charge $-\frac{1}{3}$ spin $\frac{1}{2}$ d down	mass $\approx 96 \text{ MeV}/c^2$ charge $-\frac{1}{3}$ spin $\frac{1}{2}$ s strange	mass $\approx 4.18 \text{ GeV}/c^2$ charge $-\frac{1}{3}$ spin $\frac{1}{2}$ b bottom	mass 0 charge 0 spin 1 γ photon	
	mass $\approx 0.511 \text{ MeV}/c^2$ charge -1 spin $\frac{1}{2}$ e electron	mass $\approx 105.66 \text{ MeV}/c^2$ charge -1 spin $\frac{1}{2}$ μ muon	mass $\approx 1.7768 \text{ GeV}/c^2$ charge -1 spin $\frac{1}{2}$ τ tau	mass $\approx 91.19 \text{ GeV}/c^2$ charge 0 spin 1 Z Z boson	
LEPTONS	mass $< 1.0 \text{ eV}/c^2$ charge 0 spin $\frac{1}{2}$ ν_e electron neutrino	mass $< 0.17 \text{ MeV}/c^2$ charge 0 spin $\frac{1}{2}$ ν_μ muon neutrino	mass $< 18.2 \text{ MeV}/c^2$ charge 0 spin $\frac{1}{2}$ ν_τ tau neutrino	mass $\approx 80.39 \text{ GeV}/c^2$ charge ± 1 spin 1 W W boson	

SCALAR BOSONS

GAUGE BOSONS
VECTOR BOSONS

The Big Picture – Measuring the Higgs Self-Coupling

Relevant section of the SM Lagrangian for Higgs potential:

$$V(\phi) = -\mu^2\phi^2 + \lambda\phi^4 + \dots \text{ Taylor exp. at min } \rightarrow V_T(\phi) = -\frac{\mu^4}{4\lambda} + \frac{\sqrt{2}\mu^3}{\lambda}\phi - 4\mu^2\phi^2 + 2\sqrt{2\lambda}\mu\phi^3 + \dots$$

Constant and ϕ terms: can eliminate with change of coordinates, ϕ^2 : mass term,
 ϕ^3 : self-interaction or **self-coupling** term, not well constrained
(current best: $\kappa_\lambda = (2\sqrt{2\lambda}\mu)/(2\sqrt{2\lambda}\mu)_{\text{SM}}$, $\kappa_\lambda \in [-2.3, 10.3]$ at 95% confidence)

To find κ_λ we need HH events, and we can find them using jets!

Jets and Pairing

$$H \rightarrow 60\% b\bar{b} \rightarrow 2 \times b \text{ hadrons} \rightarrow 2 \times b\text{-jets}$$

- **Jets** are collections of particles with appx. the same direction
- ATLAS can't directly detect H or b . Instead, use **b -jets**, which can be directly detected (using secondary vertices)
- b -jet detection is not a perfect process (hence 437A report), and neither is **pairing** – identifying which jets came from which H

Welcome to the Mass Plane

- **Mass plane:** reconstructed (m_{H_1}, m_{H_2}) values, m_{H_1} has higher transverse momentum
- We expect a peak around (125, 125) (all masses in GeV)
- **The Problem of Background Modelling:** how to estimate background around peak?
- Signal Region (SR): blinded to reduce study bias
- Control Region (CR): for calibrating background estimation models
- Validation Region (VR): for testing background models

The 2bRW Solution

- All jets are similar to a rough approximation
- **2b data**: uses 2 b -jets and 2 other jets
- Similar to 4b data outside of SR, but no peak
- 2bRW: derive a scaling (“ReWeighting”) function outside of SR, apply inside
- Provides a good first background estimate
- Assumes RW function applies in SR, may be false
- **This project**: is there a better approach?

Note

Don't forget 2b data is physically different from 4b and 2bRW are not **real** SR values. 2bRW is thought to be correct within around $\pm 10\%$.

New Approach: Neural Network

- Given enough data, neural networks can learn arbitrary functions
- Goal: reproduce $2bRW \pm 10\%$ using only $4b$ data
- Inputs: $(m_{H_1}, m_{H_2}, m_{HH})$, output: $P(m_{H_1}, m_{H_2})$
- Initial model: layers (10,50,50,50), 100 epochs
- Generally good-looking mass plane predictions, $2bRW$ agreement is not great though

What if we...

- Add more bins?
- Add other variables? (e.g. 7-masses, NTag)
- Smooth data (kde, polynomial, ...)?
- NTag Network
- Overall impression: hard to improve by tweaks, should try another model

New Approach: Gaussian Processes

- smooth estimator, built-in variance calculation
- relies on variogram
- variogram equation and parameters
- some ways of auto-calculating parameters, but can we do better?
- best auto-Gaussian

- Tested a bunch of variograms, insert best images
- tweaked to make variance low and flat
- tried 3d GPs fit, but won't run
- bumner: despite variance being flat, can't get variance much lower than 100%

aaaaaa

Insert a bunch of other figures

Questions?

Comments?

Any other techniques we should try?
